Magnetic Resonance Spectroscopy (MRS)

- ▶ Magnetic resonance signals from *molecules in tissue*
 - *Frequency response* to an RF signal in magnetic field (*amplitude* modulation)
 - Exploiting *spin* quantum property of nuclei (usually hydrogen / protons)
- ▶ Molecule has unique spectrum of split peaks due to
 - *Chemical shift*: frequency offset due to chemical bonds
 - *J-couplings*: splitting due to hyperfine interaction
- ▶ E.g. GABA, $H_3N^+ - CH_2 - CH_2 - CH_2 - COO^-$

MRS Quantification

- ▶ *Quantification* of (relative) molecule concentrations
 - Identify *normal/abnormal processes* in the human body
 - E.g. *early, non-invasive diagnosis* of cancer, dementia

▶ Traditional Approaches

- *Fit linear combination* of molecule spectra to signal

$$S = \sum_l c_l B_l + \epsilon$$

in frequency (LCModel, FSL-MRS) or

time (jMRUI, Tarquin) domain

- *Peak integration* (LWFIT, GANNET)

$$c_l \sim \int_{\text{freq. ranges}} S(\nu) d\nu$$

S Shermer, et al. LWFIT. 2021. <https://qyber.black/mrs/code-lwfit>

▶ Main challenges

- *Noise* from acquisition process and background signal
- *Overlapping* molecule spectra
- *Low signal strength* / low concentrations
- *Uncertainty in basis spectra*

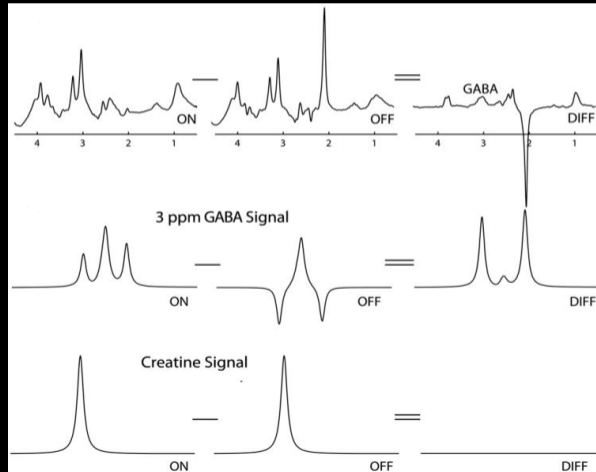

- ▶ GABA (γ -aminobutyric acid) neurotransmitter of particular interest
 - Glutamine, Glutamate, GABA, Creatine, NAA
- ▶ *Edited spectroscopy*: MEGA-PRESS

- Obtain two spectra:
 $ON - OFF = DIFF$
- ON: refocus 1.9ppm to 3ppm J-coupling
- OFF: free evolution of J-coupling
- Most other peaks are unaffected

PG Mullins, et al. Current practice in the use of MEGA-PRESS spectroscopy for the detection of GABA. Neuroimage. 86:43-52, 2014.

MRSNet - Multiclass Regression CNN

Paramtersied deep learning arch. for MRS quantification, specifically MEGA-PRESS.

input	Select([OFF, ON, DIFF], [Re, Im, Magn., Phase]) \times 2048 freq. bins 1.5 – 4.5 ppm
freq-conv1	$[f1 = 256] \times 1 \times [fc1 = 9]$ conv, $1 \times [s1 = 2]$ stride, <i>BN</i> (no DO), ReLU, <i>Pool (instead of strides)</i>
freq-conv2	$[f1 = 256] \times 1 \times [fc2 = 7]$ conv, $1 \times [s1 = 2]$ stride, <i>BN</i> (no DO), ReLU, <i>Pool (instead of strides)</i>
reduction1	$[f1 = 256] \times [2 - 3] \times [fc3 = 5]$ conv, <i>BN</i> (instead of DO), ReLU
reduction2	$[f1 = 256] \times [2 - 3] \times [fc3 = 5]$ conv, <i>BN</i> (instead of DO), ReLU
reductionX	... repeat until 1 row left (no padding)
conv1	$[f1 = 256] \times 1 \times [fc4 = 3]$ conv, <i>BN</i> (instead of DO), ReLU
conv1red	$[f1 = 256] \times 1 \times [fc4 = 3]$ conv, $1 \times [s2 = 3]$ stride, <i>BN</i> (no DO), ReLU
conv2	$[f2 = 512] \times 1 \times [fc4 = 3]$ conv, <i>BN</i> (instead of DO), ReLU
conv2red	$[f2 = 512] \times 1 \times [fc4 = 3]$ conv, $1 \times [s2 = 3]$ stride, <i>BN</i> (no DO), ReLU
dense1	$[d1 = 1024]$ FC Layer, DO2= 0.3
dense2	5 FC Layer, DO2= 0.3
output	softmax or <i>sigmoid</i> Normalised to $\sum_i c_i = 1$ or $\max_i c_i = 1$

Model Selection

- ▶ Trained on 10K (sufficient!) and 100K *simulated* spectra with 5-fold crossvalidation
 - FIDA-2D, capturing impact of gradients over 2D grid (also with FIDA-1D, lmodel, pygamma and combinations, but no improvement)
 - Gaussian noise in time domain with $\sigma = 0.03$
- ▶ *Gaussian process optimisation* (GPyOpt) to select best parameters
 - input spectra and data types
 - size of kernels, strides, dropout/batch-normalisation
 - size of fully connected output layer
 - softmax vs. sigmoid output
- ▶ Optimisation over 12×472392
 - Exhaustive search over 1K models found same result than GPyOpt within 50 iterations
 - There is a range of similarly performing models
- ▶ *MRSNet* Python3 code with all data to be released soon - <https://qyber.black/mrs/>

Best Model Performance on Simulated Test Data

Frank C Langbein
<https://qyber.black/>

Best Model Performance on Real Unseen Data

Frank C Langbein
<https://qyber.black/>

GABA Benchmark

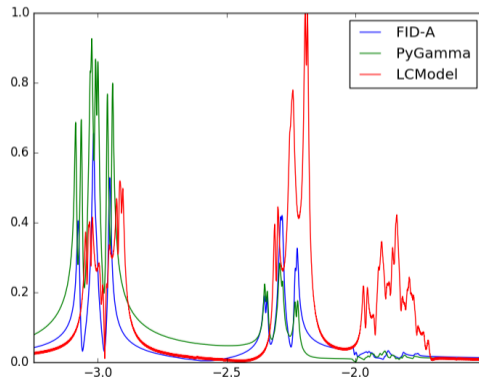

- ▶ *Performance similar to LCMoDel* gold standard, but hard to judge
 - Generally ML has not shown better results than traditional methods
- ▶ Validation via *simulated data is insufficient*
 - In-vivo behaviour in tissue may not match high-field NMR spectra in deuterium
 - Still some uncertainty in molecule models
 - Realistic noise and MR scanner characteristics
- ▶ *Ground-truth* from in-vivo data not feasible to obtain either
- ▶ *Tissue-mimicking phantoms*
scan calibrated phantoms with known concentrations
 - NAA, Cr, Glu, Gln with varying GABA concentrations
 - Background signal / macro-molecules not considered (yet!)

SM Shermer, C Jenkins, M Chandler, FC. Langbein. *Magnetic resonance spectroscopy data for GABA quantification using MEGAPRESS pulse sequence*. Data set, IEEE Data Port, 2019. DOI:10.21227/ak1d-3s20

Uncertainty in Spectral Basis

- ▶ Comparison of spectral shapes between simulators
- ▶ E.g. GABA, edit-off and edit-on

Conclusions

- ▶ *MRS* holds promise to improve non-invasive medical diagnosis and identify biochemical processes
- ▶ Presented *CNN for quantification*
- ▶ Deep learning quantification has comparable efficiency with traditional methods
- ▶ The real problem is ground truth, better data and simulators
- ▶ *Limits* – How well can we quantify molecule concentrations?
